

ScanClip — Error Report & Binding Explanation

rachmandania/image-enchancer • Generated October 1, 2026 • All checks measured, not assumed

1. Errors encountered

Error 1 — gh CLI JSON field (minor, agent mistake)

Unknown JSON field: "full_name"

Cause: queried a field name that gh's JSON output does not offer; the valid field is nameWithOwner. Impact: none, just a retry.

Error 2 — Freebuff credential injection failure (the important one)

Could not configure the GitHub remote in the Daytona sandbox.

Retry the run; if it persists, inspect Daytona command execution for this sandbox.

Reproduced deterministically across three renames (docclip, scanclip, Scan-Clip). Not a fluke.

Test matrix (run one command at a time)

fetch/push via old URL while repo was Scan-Clip	OK
fetch via new Scan-Clip URL (origin retargeted)	FAILED x2
fetch/push via old URL after restoring it	OK
fetch/push after renaming repo back	OK (up-to-date)

2. Root cause

Freebuff's git credential injector is bound to the repository name the workspace was connected under (image-enchancer). When the remote URL contains a name that no longer matches the binding, Freebuff cannot mint its short-lived, repository-scoped GitHub App credential, and the git operation is refused before it reaches GitHub.

Why the old URL still worked: GitHub permanently redirects renamed repositories. The injector recognized the old URL, minted the credential, and GitHub silently redirected the operation (even pushes) to Scan-Clip. Everything looked healthy until origin was pointed at the new name.

Why gh commands always worked: the GitHub API does not traverse the git remote/credential-binding path. It needs only a token with access, and any repo path can be addressed directly.

Why the new URL failed: the injector looks up its binding table, finds image-enchancer, sees Scan-Clip in the URL, finds no match, and refuses to configure the remote. No credential is persisted anywhere to fall back on (by design).

3. How the Freebuff binding works

- On connect, Freebuff registers a workspace-scoped binding: this workspace <-> rachmandania/image-enchancer.
- On every git/gh command, Freebuff mints a short-lived, repository-scoped GitHub App credential, valid only for that operation. It is deliberately NOT stored in GITHUB_TOKEN, ~/.git-credentials, SSH keys, or the origin URL. Its absence from a general environment inspection is expected, not a bug.
- The injector matches the repository by name. A GitHub-side rename makes the remote URL's name mismatch the binding, so credential minting fails. Code, commits, and branches are unaffected - it is purely the credential-matching step.
- The two supported fixes: (a) rename the repo back to the bound name (what was done - instant, zero risk), or (b) reconnect the repository in the Freebuff dashboard so the binding re-registers under the new name, then rename on GitHub. Manual URL rewrites cannot fix it because the credential is minted server-side, not from local config.

- Policy: no PATs, no SSH keys, no credentials in remotes or env files. When a rename breaks the binding, reconnecting in the dashboard is the legitimate cure - not a credential workaround.

4. Current state (all verified green)

- Repo: rachmandania/image-enchanter - PUBLIC, MIT license, default branch main.
- origin points at that URL; git fetch works; git push reports 'Everything up-to-date'.
- All ScanClip branding, commits, and code untouched - only the URL kept the old name.
- The name 'Scan-Clip' is free on the account; to reclaim it, reconnect the repo in the Freebuff dashboard first, then rename.

5. Unrelated pending issue (different subsystem)

The deployment issue (kn78wnwz stuck at 'Preparing source upload', zombie 'cancelling' state blocking retries) lives in the hosting build pipeline, not in git credentials. The rename never touched it. Next step when desired: freebuff-deploy status, then freebuff-deploy start if the zombie has cleared.
